

What is the actual power of a laser diode

Overview

The optical power value, P_o , is the most basic characteristic of a laser diode. This parameter is defined as the light output intensity in the case that a specific current is applied to the device in the forward direction, and is typically expressed in units of W. Precautions required to avoid excessive currents, static electricity and heat generation are detailed and the drive. A laser diode is a small semiconductor gadget that produces strong and precise light emissions through a cycle called stimulated emission. These gadgets track down wide applications because of their proficiency and minimal size. They are offered in an industry standard butterfly package which has a single mode fiber output terminated with an FC/APC connector. Accordingly it is necessary to understand the main laser diode specifications and characteristics and how they can relate to real electronic. This calculator determines the optical output power of a laser diode based on its threshold current, slope efficiency, and drive current.

A laser diode is electrically a PIN diode. The active region of the laser diode is in the intrinsic (I) region, and the carriers (electrons and holes) are pumped into that region from the N and P regions respectively. While initial diode laser research was conducted on simple P-N diodes, all modern lasers use the double-hetero-structure implementation, where the carriers and the photons are confined in order to maximiz...
